III. CONCEPT AND METHODS

A. Business Models

Who develops the CPU cores, how can you get access to them? Who supports chip manufacturers in designing a chip with that CPU core?

B. Complexity (written by Michael Schneider)

Risc-V and ARMv8 are both Reduced Instruction Set Computer (RISC) based architectures and compared to Complex Instruction Set Computer (CISC) they are much more limited and all operations are based on register. RISC machines are having a lot of characteristics, which are not necessary to be completely implemented, but they can lead to a few advantages of RISC compared to CISC, like an simpler control unit and faster decode. [1]
Even various RISC Instruction Set Architectures (ISAs) are different in complexity. To compare those differences, the basic Instruction sets with corresponding extensions, the different realisations and two basic assembly instructions will be viewed in the next chapters.

1) Instruction sets: In RISC-V the only necessary Instruction set is the Integer instruction set. Those base integer instructions cannot be redefined, only extended by optional instruction sets. Additional to operations for the base ISA, completely different extensions are available. Further details are in chapter III-D. This concept makes the RISC-V architecture only as complex as necessary, because all the gratuitous instructions are not implemented. [2]
ARM instead is defining the ARMv8 architecture in a completely different way. The ARMv8 supports already much more extensions in the basic version, also called v8.0. Further

extensions are available in higher versions, which are granular explained in the chapter III-D. [3]
Because almost all the optional extensions of RISC-V are covered by the basic v8.0, the ARMv8, only from the instructions set of view, is at least as complex as a fully extended RISC-V architecture.

2) Instruction set implementations: The different ISAs are able to implement the explained instruction sets in various ways. The RISC-V architecture is able to implement the instruction sets in 3 different versions a 32-bit (RV32I), a 64-bit (RV64I) and a 128-bit version (RV128I). For the 32-bit and the 64-bit implementations are also multiple subversions available, RV32E and RV32G/RV64G. For 128-bit RV128I is the only 128-bit implementation so far. RV32I is a version with only 15 instead of 31 registers. The subversion RV32G/RV64G is less a own version than a stable release. The RV32G/RV64G is combining a basic ISA (RV32I or RV64I) plus different selected standard extensions (IMAFD). [2]
Also ARMv8 has, as expected, different implementations, A64, A32 and T32. As mentioned A64 is the 64-bit version and A32, T32 are both 32-bit versions. AARCH64 and AARCH32 are two different execution states in ARM (AARCH64 for 64-bit and AARCH32 for 32-bit). These execution states are supporting the A64 instruction set in AARCH64 and A32 and T32 in AARCH32. [3]

3) registers and access: To complete the overview in an maybe for users more abstract point of few, the basic assembler commands (load and read) are compared. To load an value from the RISC-V register LW, LH or LB is called. The "L" means load and the following characters stand for word (32 bit), halfword (16 bit) and byte. All are built-on the same way and LH and LB can be extended by an "U" (LHU, LBU) to load them as an unsigned value. All instructions are taking 2 parameters, a temp register to store the value in and an address to load the value from. The address is a pointer to the register together with an offset. In the same way the store instructions SW, SH and SB are working. SW means store word, SH store halfword and SB means store byte. The built-on is the same way as it is for the loading. But the left side of the command is the temp register to take the value from and the second parameter is the register to store the value in (again with an offset). [2]
ARM instead has a few more instructions but the basics are almost the same. The (LDR) command can be extended by an B to load only an byte, SB to load a signed byte, H to load a half word, SH to load an signed halfword and SW to load a signed word. To store a value in a register there

are 3 possible ways STR to store complete register, STRB to Store byte, STRH to store halfword. These basic load and store commands are followed by a few more, to load/store pairs, non temporal pairs, unscaled offsets and much more. Because there is not such an possibility in RISC-V there is no comparison about them. [3]

C. Performance

What are the differences in code size? Can we accurately compare the execution speed of both ISAs?

D. Extensibility

What instruction set extensions are there for both ISAs? Who can develop new extensions?

E. Ecosystem

Which compilers support ARM and RISC-V? Which operating systems and libraries?

IV. DISCUSSION

A. ARM

What are the advantages of ARM compared to RISC-V?

B. RISC-V

What are the advantages of RISC-V compared to ARM?

C. Future directions and challenges

How can we more accurately measure performance differences between ARM and RISC-V and how do ISA extensions affect performance?

V. CONCLUSION AND OUTLOOK

A. Summary of results

B. Accuracy of results

C. Future directions
